## Chapter 4

## Network Layer

## 4-1 INTRODUCTION

- Figure 4.1 shows the communication between Alice and Bob at the network layer.
- This is the same scenario we used in Chapters 2 and 3 to show the communication at the application and the transport layers, respectively.

## Figure 4.1: Communication at the network layer

## Network-Layer Services

The network-layer services that, in general, are expected from a network-layer protocol.
$\square$ Packetizing
$\square$ Routing
$\square$ Forwarding

## Figure 4.2: Forwarding process

## Packet Switching

- A kind of switching occurs at the network layer
- A router is a switch that creates a connection between an input port and an output port (or a set of output ports), just as an electrical switch connects the input to the output to let electricity flow.

## - Datagram Approach

# $\square$ Virtual-Circuit Approach

## Network-Layer Performance

- The upper-layer protocols that use the service of the network layer expect to receive an ideal service, but the network layer is not perfect
- The performance of a network can be measured in terms of delay, throughput, and packet loss.

## $\square$ Delay

# * Transmission Delay <br> * Propagation Delay <br> * Processing Delay <br> Queuing Delay 

$\square$ Throughput
$\square$ Packet Loss

TR: Transmission rate

## Figure 4.12: Effect of throughput in shared links

TR: Transmission rate

## Structure of A Router

- accepts incoming packets from one of the input ports (interfaces)
- uses a forwarding table to find the output port from which the packet departs
- sends the packet from this output port.

Figure 4.34: Information extraction in classless addressing

## Any address

Number of addresses:

$$
\mathrm{N}=2^{32-n}
$$

## Example 4.1

A classless address is given as 167.199.170.82/27. We can find the above three pieces of information as follows. The number of addresses in the network is $2^{32-} n=2^{5}=32$ addresses. The first address can be found by keeping the first 27 bits and changing the rest of the bits to 0 s.

| Address: $167.199 .170 .82 / 27$ | 10100111 | 11000111 | 10101010 | 01010010 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| First address: $167.199 .170 .64 / 27$ | 10100111 | 11000111 | 10101010 | 01000000 |

The last address can be found by keeping the first 27 bits and changing the rest of the bits to 1 s .

```
Address: 167.199.170.82/27
```

```
10100111 11000111 10101010 01011111
```

10100111 11000111 10101010 01011111
10100111 11000111 10101010 01011111

```
10100111 11000111 10101010 01011111
```

## Example 4.2

We repeat Example 4.1 using the mask. The mask in dotteddecimal notation is 256.256 .256 .224 The AND, OR, and NOT operations can be applied to individual bytes using calculators and applets at the book website.

$$
\begin{array}{ll}
\hline \text { Number of addresses in the block: } & \mathrm{N}=\text { NOT }(\text { mask })+1=0.0 .0 .31+1=32 \text { addresses } \\
\text { First address: } & \text { First }=\text { (address) AND (mask) }=167.199 .170 .82 \\
\text { Last address: } & \text { Last }=\text { (address) OR }(\text { NOT mask })=167.199 .170 .255 \\
\hline
\end{array}
$$

## Figure 4.35: Network address

## Example 4.4

An ISP has requested a block of 1000 addresses. Since 1000 is not a power of 2,1024 addresses are granted. The prefix length is calculated as $n=32-\log _{2} 1024=22$. An available block, $18.14 .12 .0 / 22$, is granted to the ISP. It can be seen that the first address in decimal is $302,910,464$, which is divisible by 1024 .

## Example 4.5

An organization is granted a block of addresses with the beginning address $14.24 .74 .0 / 24$. The organization needs to have 3 subblocks of addresses to use in its three subnets: one subblock of 10 addresses, one subblock of 60 addresses, and one subblock of 120 addresses. Design the subblocks.

## Solution

There are $2^{32-24}=256$ addresses in this block. The first address is $14.24 .74 .0 / 24$; the last address is $14.24 .74 .255 / 24$. To satisfy the third requirement, we assign addresses to subblocks, starting with the largest and ending with the smallest one.

## Example 4.5 (continued)

a. The number of addresses in the largest subblock, which requires 120 addresses, is not a power of 2 . We allocate 128 addresses. The subnet mask for this subnet can be found as $n_{1}=32-\log _{2} 128=25$. The first address in this block is 14.24.74.0/25; the last address is 14.24.74.127/25.
b. The number of addresses in the second largest subblock, which requires 60 addresses, is not a power of 2 either. We allocate 64 addresses. The subnet mask for this subnet can be found as $n_{2}=32-\log _{2} 64=26$. The first address in this block is $14.24 .74 .128 / 26$; the last address is 14.24.74.191/26.

## Example 4.5 (continued)

c. The number of addresses in the largest subblock, which requires 120 addresses, is not a power of 2 . We allocate 128 addresses. The subnet mask for this subnet can be found as $n_{1}=32-\log _{2} 128=25$. The first address in this block is 14.24.74.0/25; the last address is 14.24.74.127/25.

If we add all addresses in the previous subblocks, the result is 208 addresses, which means 48 addresses are left in reserve. The first address in this range is 14.24.74.208. The last address is 14.24 .74 .255 . We don't know about the prefix length yet. Figure 4.36 shows the configuration of blocks. We have shown the first address in each block.

## Figure 4.36: Solution to Example 4.5

## Example 4.6

Figure 4.37 shows how four small blocks of addresses are assigned to four organizations by an ISP. The ISP combines these four blocks into one single block and advertises the larger block to the rest of the world. Any packet destined for this larger block should be sent to this ISP. It is the responsibility of the ISP to forward the packet to the appropriate organization. This is similar to routing we can find in a postal network. All packages coming from outside a country are sent first to the capital and then distributed to the corresponding destination.

## Server name

## Boot file name

## Options

## Fields:

Opcode: Operation code, request (1) or reply (2)
Htype: Hardware type (Ethernet, ...)
HLen: Lengh of hardware address
HCount: Maximum number of hops the packet can travel
Transaction ID: An integer set by client and repeated by the server
Time elapsed: The number of seconds since the client started to boot Flags: First bit defines unicast ( 0 ) or multicast (1); other 15 bits not used Client IP address: Set to 0 if the client does not know it
Your IP address: The client IP address sent by the server
Server IP address: A broadcast IP address if client does not know it Gateway IP address: The address of default router
Server name: A 64-byte domain name of the server
Boot file name: A 128-byte file name holding extra information Options: A 64-byte field with dual purpose described in text

## Figure 4.84: Format of path attribute

O: Optional bit (set if attribute is optional)
P: Partial bit (set if an optional attribute in lost in transit)
T: Transitive bit (set if attribute is transitive)
E: Extended bit (set if attribute length is two bytes)

| 10 |  |  |  |  | \|8 | \|16 | \|24 | 31 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| O | T | P | E | All 0s | Attribute type | Attribute value length |  |  |
| Attribute value (variable length) |  |  |  |  |  |  |  |  |

## Figure 4.85: Flow diagram for route selection

## Figure 4.86: BGP messages

Notification message (type 3)

Update message (type 2)

Keepalive message (type 4)
Fields in common header
Marker: Reserved for authentication
Length: Length of total message in bytes
Type: Type of message (1 to 4)
Abbreviations
O len: Option length
EC: Error code
ES: Error subcode
UR len: Unfeasible route length
PA len: Path attribute length
